

G.20 Exercise

Review question: What is the effectiveness of programmes of exercise in the management of cystic fibrosis?

Study details	Participants	Interventions	Methods	Outcomes and Results	Comments

<p>Blood Institute grant HL52306, and in-kind support from the Center for Behavioral Epidemiology and Community Health, Graduate School of Public Health, San Diego State University.</p>	<p>on more than one baseline testing date.</p>	<p>rate to 70% of their maximum heart rate Intervention 2. Upper-body strength training regimen Each child was given an upper-body-only-weight-resistance machine Participants were encouraged to exercise at least 3 times per week for 1 year Counselors conducted in-home visits once a week for the first 8 weeks followed by monthly visits for the remainder of the study Participants were instructed to perform biceps curls,</p>	<p>pedaling at 0 W for 1 min, with the workload increasing by 10 W, 15 W, or 20 W each minute depending on the patients' height and clinical status. Maximal effort was encouraged. The peak work capacity was defined as the highest workload (watts) sustained for 1 min, and peak work capacity percentage of predicted was determined from the equations of Godfrey based on height and gender. Metabolic equipment (Medical Graphics; St. Paul, MN) provided online, breath-by-breath measures of oxygen uptake. Peak values were determined from the last 15 s of exercise. A 12-lead ECG was monitored continuously, and heart rate was determined each minute and at peak exercise. Pulmonary Function Testing: Prior to exercise testing, participants performed pulmonary function tests according to the American Thoracic Society standards. Lung volumes were determined by body plethysmography. Spirometry, including flow volume curves both before and after inhalation of a bronchodilator (albuterol), was performed using a body plethysmograph (Sensor Medics System 6200; SensorMedics; Yorba Linda, CA), with the patient seated comfortably. FVC and FEV1 were chosen from among no fewer than</p>	<p>at baseline: 32.64 (6.22) Body composition Not reported Quality of life Not reported Time to next exacerbation Not reported Preference for training programme Not reported Adverse events Not reported</p>	<p>Incomplete outcome data (attrition bias) (all outcomes): Low risk (intention-to-treat analysis was employed. Only subjects with data at both time points were included: 56/67 and 53/67 for the 6-month and 12-month follow-up respectively) Selective reporting (reporting bias): Low risk (The authors mention that measures were obtained at baseline, at 6 months and at 12 months and report outcomes at all these follow-ups) Other bias: Low risk (not detected) Other information</p>

Intervention 1: ≥30 minutes daily of habitual moderate-vigorous physical activity Control 1: <30 minutes daily of habitual moderate-vigorous physical activity</p>	<p>Details Setting. Two specialist CF centres in Melbourne. Recruitment. When attending a routine outpatient appointment, people were invited to participate in the study by a research physiotherapist not involved in their clinical care. Data collection. Physical activity was measured over 5-7 days using a portable multi-sensor armband, the SenseWear Pro3 Armband (SWA); the armband has been validated for assessing land-based PA intensity in adults with CF. Moderate physical activity intensity was classified as ≥4.8 metabolic equivalents. Data analysis. Physical activity data were</p>	<p>Results Need for hospitalization* Intervention 1: 16/33 vs control 1: 19/28 Intervention 2: 8/21 vs control 2: 26/40 *Please note that this was the only outcome that was extracted from this cohort study because this outcome can be considered a proxy for time to next exacerbation, which is a critical outcome</p>	<p>Limitations The quality of this study was assessed using the Newcastle-Ottawa scale assessment tool Selection of study population: High risk of bias Representativeness of the exposed cohort: Truly representative of the average people with CF that fit the inclusion criteria of the study</p>
