

D.7.2 Managing dopaminergic treatment in people who have developed impulse control disorder

Study details	Participants	Methods	Results	Comments
<p>Full citation Okai,D., Askey-Jones,S., Samuel,M., O'Sullivan,S.S., Chaudhuri,K.R., Martin,A., Mack,R.J., Brown,R.G., David,A.S., Trial of CBT for impulse control behaviors affecting Parkinson patients and their caregivers, Neurology.80 (9) (pp 792-799), 2013.Date of Publication: 26 Feb 2013., 792-799, 2013</p> <p>Ref Id 308530</p> <p>Country/ies where the study was carried out UK</p> <p>Study type RCT of CBT</p> <p>Aim of the study to test the effects of a novel CBT-based intervention delivered by a nurse therapist to patients with PD with clinically significant impulse control behaviours</p>	<p>Sample size N= 45 diagnosis of PD ; treatment n=28; waitlist n=16</p> <p>Inclusion criteria diagnosis of PD according to UKBB criteria and associated ICB which had failed to remit despite measures taken by treating neurologist, including medication changes</p> <p>Exclusion criteria participants were excluded if did not meet inclusion criteria (n=11). standardized MMSE score <24, non english speakers, those without n identifiable carer able to participate in the trial</p>	<p>Details ICB screened using QUIP. following screening, ICD confirmed by clinical interview which made us of DSM IV criteria for pathological gambling, along with other criteri for the ICB</p> <p>Eligible consenting participants were randomly assigned to immediate treatment or 6 month waiting list</p> <p>randomization via random number tables held independently of those performng the initial clinical assessment</p> <p>those randomized to treatment started immediate;y with intention to see people weekly for 12 sessions of treatment patients nd rather were aware of location following randomization</p> <p>Interventions treatment - CBT treatment manual was compiled during the pilot phase of the trial and informed by currently published treatment of ICDin general population adapted for a PD population, with additional components of communication and interpersonal relationships</p>	<p>Results demographics mean age; treatment = 59.3 years (8.1), control = 57.9 (9.5) male sex 19; treatment (67.9%), control 12 (70%) duration of PD; treatment 10.5 (6.0), control 8.8 (5.6) duration of ICB; treatment 4.4 (3.2), control 3.8 (4.6)</p> <p>Study data all patients completed t least one session in group and were completed in the analysis; 58% completed all and 88% completed at least 6 sessions No significant differences between groups based on demogrpahic and clinical characteristics, nor was there a difference in use of dopamine agonists or ledd. Total UPDRS scores were similar across treatment groups and remained stable over the course of treatment There was a significant effect with regard to changes in global levels of symptom severity using CGI as continuous measure with reduction in tmt group. 75% improved in treatment group compared to 29% in waitlist group The frequency and impact of ICB was significantly reduced over time in the treatment group. additionally there was an improvement in anxiety and depression in treatment group. GHQ-28 scores were significantly better in tmt gropou. GRIMS indicated no treatment effect on</p>	<p>Overall Risk of Bias</p> <ol style="list-style-type: none"> 1. An appropriate method of randomization was used to allocate pts to treatment groups? yes - via independent random number table 2. There was adequate concealment of allocation no - not possible. patient, nurse, clinician qnd family all informed of allocation. The groups were comparable at baseline, including all major confounding and prognostic factors? yes 4. Comparison groups received same care apart from interventions. waitlist control received no care 5. Pts receiving care were kept blind to tmt allocation no - not possible 6. Individuals administering care were kept blind to tmt allocation no not

Inclusion criteria were ideopathic PD by UKBB criteria, capacity to provide written informed consent and ability to complete a series</p>	<p>Details Subjects followed under routine clinical care and followed prospectively until they reached first of the following pre determined end points: new onset of ICD discontinuation of DAA therapy death or loss to follow up June 30, 2011 Only those who received a predefined minimum exposure to DAA after study enrollment (at least 50 L-dopa equivalent daily dose (LEDD) of DAA for 3 months or more consecutive months) were included within the analysis.</p>	<p>Results frequency and characteristics of ICD 164 patients enrolled in study, of whom 46 subsequently treated with minimum dosage and duration of DAA therapy for inclusion in analysis of these 46, 18 (50% female) developed ICD's after mean duration 21.0 months 6 subjects with ICD lost to follow up mean ICD-free survival time was 68 months (95% CI: 34.8 to 101.2) most common ICD compulsive eating (16/18); 6/18 hypersexuality; 5 compulsive shopping/buying, 1 compulsive gambling concomitant punding present in 12/18 no ICD (-) patients reported punding behaviours time of onset ICD highly variable (range 3 months to 10 years, median 23 months) after initiation of DAA therapy and 1 to 19 years after PD onset diagnosis delayed from between 0 - 15 months after ICD onset (median 4 months)</p>	<p>Overall Risk of Bias</p> <ol style="list-style-type: none"> Did study address on clearly focused issue? yes Was cohort recruited in acceptable way? yes - consecutive Was exposure accurately measured to minimise bias? yes Was outcome accurately measured to minimise bias? yes Have authors identified all important confounding factors and taken account of these in design/analysis? yes Was follow-up of subjects complete/long enough? yes - follow up until reach one of pre-defined end points 			

Study details	Participants	Methods	Results	Comments
<p>Aim of the study To study prospective incidence time course and risk factors of ICD's</p> <p>Study dates received 9th augus 2012, revised Oct, published Jan 2013</p> <p>Source of funding The study was supported by a centre grant from the PD foundation</p>	<p>of research questionnaires</p> <p>Exclusion criteria Previous history of ICD, atypical clinical features, MMSE score of <25, clinical diagnosis of dementia, life expectancy of <12 months use of dopaminergic receptor blocking agent, or previous PD neurosurgery</p>	<p>at baseline all subjects avaluated by movement diorder neurologist who completed series of assessments including UPDRS, ADL, MMSE, depression inventory, medication and family history</p> <p>assessment for presence of ICD and punding behaviours occurred at baseline visit and each subsequent visit using semistructured interview involving the subject and all available caregivers interview included broad questions to identify symptoms suggestive of an ICD. If a subject endorsed one or more repetitive behaviours then follow-up questions were asked to determine the scope and consequences of these behaviours . Behaviours classified as ICD's if they disrupted normal work, family, or social interaction or casued negative medical or psychological consequences.</p>	<p>in 4 subjects (22.2%), incidence of ICD elucidated only through 66.7%)of caregiver or other outside observer risk factors/baseline characteristics</p> <p>baseline demographic characteristics similar between both groups</p> <p>ICD+ grop had significantly higher prevalence of smoking (44.4% vs 14.3%) and also higher caffeine use (100% vs 66.7%)</p> <p>previous alcoholism rare and same across both groups (88.9% vs 64.3%)</p> <p>at baseline ICD group greater prevalence of motor complications (61.1% vs 25.0%)</p> <p>in contrast, no significant differenes in UPDRS quantitative and qualitiative use of dopaminergic medication same across both groups as was antidepressant and benzodiaepine use</p> <p>trand toward greater familyh istory of depression in ICD group (11.1%vs 32.1%)</p> <p>endpoint characteristics</p> <p>at endppoint major difference between ICD+/- groups was higher peak DAA dosage in ICD+ grop (median 300 vs 165 LEDD)</p> <p>disease duration. DAA treatment duration, cumulative DAA exposure, specific DAA used, concomittant L-dopa, total LEDD and durattion of dopaminergic therapy were comparable between groups</p> <p>Outcomes in ICD + subjects. ICD resolved in: 10/10 subjects discontinued DAA usage 3/5 reduced DAA dosage 0/3 who continued same dosage</p> <p>concomittent punding occured in 12/18 patients with ICD and resolved in: 5/5 who discontinued DAA therapy 2/4 who reduced DAA dose</p>	<p>7. What are results? study found number of predictive factors for ICD's in prospective cohort 8. How precise are results? only raw data and p- vlaues given. OR's calculated where possible. 9. Are results believable? yes 10. Can results be applied to local population? yes , however all subjects were taking DA. May not be appropriate for patients not taking DA 11. Do results fit with other available evidence? yes 12. What are implications for practice? advise patients taking DA of increased risk of ICD</p> <p>low risk of bias</p>

Study details	Participants	Methods	Results	Comments
		<p>ICD status determined at time of each visit, and data on medication usage, caffeine consumption and cigarette smoking behaviours also recorded.</p> <p>Interventions NA</p>	<p>0/3 who continued same dose dopamine agonist withdrawal syndrome (DAWS) occurred in: 6 of ICD subjects; 4 who discontinued use; 1 who reduced dose; 1 who was unable to decrease DAA dose because of severity of DAWS symptoms 4/5 subjects with DAWS developed DDS as they self adjusted l-dopa in unsuccessful attempt to alleviate DAWS symptoms</p>
