<p>Reynolds,M.R., Ray,W.Z., Strom,R.G., Blackburn,S.L., Lee,A., Park,T.S., Clinical outcomes after selective dorsal rhizotomy in an adult population, World Neurosurgery, 75, 138-144, 2011</p> <p><b>Ref Id</b></p> <p>132414</p> <p><b>Country/ies where the study was carried out</b></p> <p>USA</p> <p><b>Study type</b></p> <p>Before and after study</p> <p><b>Aim of the study</b></p> <p>To evaluate the effectiveness of SDR for adults with CP related spastic diplegia.</p> <p><b>Study dates</b></p> <p>1989 - 2007</p> <p><b>Source of funding</b></p> <p>No commercial or financial relationships influenced the content of the article.</p>	<p>N=21</p> <p><b>Characteristics</b></p> <p>Age: mean 26 years (range 18 to 39 years)</p> <p>Ambulant (GMFCS I to III): 21/21 - all had independent ambulation with or without an assistive device</p> <p>Non-ambulant (GMFCS IV or V): 0/21</p> <p>Degree of dystonia / spasticity:</p> <p>Prior treatment with baclofen pump:</p> <p>Adjunct medications:</p> <p>Presence of scoliosis:</p> <p><b>Inclusion criteria</b></p> <p>Patients treated by a single surgeon (1989 - 2007) who had cerebral palsy-related spastic diplegia, with independent ambulation with or without an assistive device, and relatively mild orthopedic deformities. All had disabilities which were an obstacle toward achieving an acceptable quality of life. A subjective assessment was</p>	<p>Selective dorsal rhizotomy</p>	<p>The T12-L1 level was verified by plain radiographs of the thoracolumbar junction. After a single-level laminectomy, the conus medullaris was localized under ultrasonographic guidance before dural opening. The operating microscope was then used to separate the dorsal nerve roots from the ventral roots. After identification of the L2-S2 dorsal roots, electromyographic testing was performed to ensure that no ventral roots were included. Electromyographic studies were used to examine the innervation pattern of individual roots. Subsequently, each root was subdivided into three to five rootlets, which were tested in a stepwise fashion and graded for reflex threshold. Rootlets that produced excessive responses were cut. At least 25% to 33% of the rootlets were preserved at each level to avoid a postoperative sensory deficit.</p> <p>Patients were evaluated preoperatively several days before surgery and postoperatively at 4 months. Most patients (11/21) participated in longer periods of postoperative follow-up (mean, 17.6 ± 30.2 months; range, 4-138</p>	<p>Walking</p> <p>Gross motor function</p> <p>Tone</p> <p>Health related quality of life</p> <p>Pain</p> <p>(follow up 4 months – for objective physical assessment; mean 5 years for function self-assessment)</p> <p><b>Results</b></p> <p>See forest plots in appendix E</p>	<p>EPOC Quality criteria for interrupted time series (ITS)</p> <p>Protection against secular changes - done</p> <p>Data were analysed appropriately - done</p> <p>Sample size calculation performed - not done</p> <p>Shape of the intervention effect was specified - not clear</p> <p>Protection against detection bias: Intervention unlikely to affect data collection - done</p> <p>Protection against detection bias:</p>

	<p>performed for those patients exhibiting the highest potential for functional gain after SDR and motivation to perform a home exercise program</p> <p><b>Exclusion criteria</b></p> <p>Not reported.</p>		<p>months). Assessments included baseline ambulatory status, joint ROM, GMFM, degree of spasticity, and adequate conservative therapy. Studies of joint ROM were performed with the use of a 360-degree goniometer . Muscle tone was quantified by use of the modified Ashworth scale.</p> <p>Each patient completed a telephone survey of subjective pre- and postoperative function. All surveys were conducted during the month of July 2007 (62.3 ± 37.4 months after SDR surgery; range, 9-132 months after SDR surgery). The survey consisted of 48 questions, including “pre-operative chief complaint” and “functional status following surgery” (improved, no change, or worse).</p> <p>Assist devices required for ambulation were also assessed pre- and postoperatively. Patients were instructed to estimate the time required to walk 10 feet before and after SDR surgery. Patients were asked to rate the following on a scale of 0 to 10 preoperatively versus postoperatively: ambulatory ability, spasticity, coordination, joint ROM,</p>		<p>Blinded assessment of primary outcome(s) - not clear</p> <p><b>Other information</b></p> <p>Not applicable</p>
